CHAPTER 1

Resen

Resen (REproducible Software ENvironment), is a tool that enables reproducible scientific data analysis, built using python and docker. It is designed to make it easier for geospace researchers to share analysis and results, as well as build off of work others have done. Resen was developed under the InGeO project, currently supported by the National Science Foundation's Cyberinfrastructure for Sustained Scientific Innovation (CSSI) program (Grant #1835573). For more information about the InGeO project, please visit the InGeO website.

Resen is based on the concept of portable environments, or buckets, where code can be developed and run independent of a users system. When you start a resen bucket, it has a variety of common geospace software packages preinstalled and ready for use. This means you have easy access to common models and datasets, and can start using them in your analysis immediately. You can also set up your bucket to access your own datasets, locally stored on your machine.

After you have completed your analysis, you can share an entire bucket with other researchers. Within the bucket, your analysis code will always run exactly the same way, regardless of what system the bucket is on. This means that other researchers should be able to reproduce your work and start building off of it immediately, instead of spending time configuring their system, installing new packages, and setting up file paths so their environment is compatible with your code.

1.1 Quickstart

1.1.1 Installation

Resen requires both python 3 and docker to be installed.

- 1. Install Python 3
- 2. Install docker
- 3. Clone the resen git repository and install with ${\tt pip}$ install .

Please refer to the installation documentation for more detailed instructions.

1.1.2 Usage

Resen is a command line tool. To start resen, simply enter resen at a command prompt:

\$ resen

For a list of available commands, use the help command:

[resen] >>> help

Resen Workflow Example

1.2 Documentation

Complete documentation for Resen is available at https://resen.readthedocs.io/.

CHAPTER 2

Installation

2.1 Gerneral Instructions

Resen is built off of both python 3 and docker, so you must have both of these installed for Resen to function.

2.1.1 Python 3

Python (https://www.python.org/) is an open source, interpreted programming language that is both powerful and easily to learn. There are many ways you can install python on your system. For new users, we recommend downloading and installing the latest Python 3 Anaconda Distribution (https://www.anaconda.com/distribution/) for your system. This will save you the trouble of building a python distribution from scratch.

2.1.2 Docker

Docker CE is the recommended version of Docker to use with Resen. Installation instructions can be found in the docker documentation. Please read installation instructions carefully! For convenience, some OS specific links are provided below:

MacOS: Install Docker Desktop for Mac

Important! Docker Desktop is only for MacOS 10.10 Yosemite and later. Earlier versions of MacOS should install Docker Toolbox.

Windows: Install Docker Desktop for Windows Important! If you are already using virtualbox, do NOT install Docker Desktop. Instead, install Docker Toolbox.

CentOS: Get Docker CE for CentOS

Debian: Get Docker CE for Debian

Fedora: Get Docker CE for Fedora

Ubuntu: Get Docker CE for Ubuntu

2.1.3 Resen

Install Resen from a python 3 environment using pip:

pip install git+https://github.com/EarthCubeInGeo/resen.git@v2019.1.0

2.2 Windows Gotchas

Resen requires both python 3 and docker to function. Here we provide a basic guide for installing both python 3 and docker. We have tested this procedure and know it works. Python 3 and Resen are easy to install. Docker is also fairly easy, but there are some subtle details that need to be emphasized for a smooth installation process.

2.2.1 Install Anaconda and Resen

Anaconda: We recommend downloading and installing the Python 3 Anaconda Distribution (https://www.anaconda. com/distribution/). This simplifies the installation and usage of several common software tools needed to install and run Resen.

Resen: Using the start menu search, open the "Anaconda Powershell Prompt" and install Resen using pip:

pip install git+https://github.com/EarthCubeInGeo/resen.git@v2019.1.0

Once complete, this will provide the command line command resen. Next, we need to install Docker.

2.2.2 Docker

For Windows, there are 2 options for installing Docker, which depends on what else you use and do with your Windows system:

- 1. Docker Desktop for Windows
- 2. Docker Toolbox

If you use Oracle VM VirtualBox to run virtual machines on your Windows system, DO NOT install Docker Desktop. You must instead install Docker Toolbox. Docker Desktop uses Hyper-V, which is not compatible with VirtualBox.

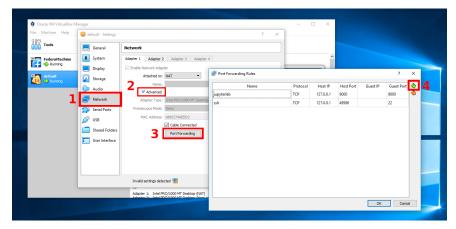

Docker Desktop TODO. If you can help fill this in, please make a PR to the develop branch for resen!

Docker Toolbox Docker Toolbox essentially works by running docker inside of a Linux virtual machine using VirtualBox. The VM that gets installed is name "default" and we will refer to this "default" Docker virtual machine as the "Docker VM". To install it Docker Toolbox, do the following:

- 1. Shutdown any VirtualBox VMs that you currently have running and take note of the VirtualBox version you have installed. Docker Desktop installs an older version of VirtualBox on your system, but this version you are currently running can be upgraded back to the version you are currently running.
- 2. Follow the instructions on here to install Docker Toolbox. Once installed, restart your computer and then run the Docker Quickstart Terminal from the start menu. TODO: insert screenshot
- 3. Now we need to add port forwarding and check the shared folders for the Docker VM in VirtualBox. To do this, open VirtualBox and open the "Settings" for the "default" VM, like so:

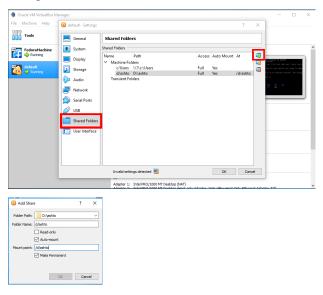

Oracle VM VirtualBox Manager File Machine Help	- 🗆 X
Tools	New Settings Discard Show
FedoraMachine	General Preview American default
default Running	Operating System: Linux 2.6 (3.x / 4.x (64-bit) Education and the second
	System Base Henry: 124:465 Base Henry: 124:465 Base Menry: 12
	Display Vides Memory: 8 MB regrins Convolute Videx/MA Remote Desitiop Server: Dashed Recording: Dashed
	Storage SATA Pri 1: dbpcal Drivel biost2doder iso (45.00 MB) SATA Pri 1: dbpcamb (19.53 GB)
	Dest Driver: Windows DirectSound
	Controller: ICH AC97 I Network
	Adapter 1: Intel PRO/1000 MT Desktop (NAT) Adapter 2: Tatel DDO (1000 ATT Desktop (Nat)

Add a new port forwarding rule by navigating to Settings->Network->Adapter 1->Advanced->Port Forwarding:

Here, we need to add a port forwarding rule for each bucket we create in Resen. Resen requires port 9000 for one bucket and then increments by 1 for every new bucket created. This means that if you have 5 buckets, you will need to make a port forward rule for ports 9000, 9001, 9002, 9003, and 9004. Change both the Host and Guest Ports as seen in the above screenshot.

Now we can optionally add Shared Folders. By default, Docker Toolbox shares the C:\Users directory with the Docker VM at /c/Users. This means that directories in C:\Users will be available to mount into a Resen bucket via the /c/Users Shared Folder in VirtualBox. If additional shared directory locations are desired add them. For example:

makes an additional location, D:\ashto available to the Docker VM at the location /d/ashto so that any directories in D:\ashto can be mounted into a resen bucket via /d/ashto. After adding or removing Shared Folders, you must restart the Docker VM. This can be done by running:

docker-machine restart

in the "Docker Quickstart Terminal".

4. Optionally, you can now re-install the newer verions of VirtualBox that you had previously installed. Before doing this, shutdown the Docker Toolbox VM. After re-installing VirtualBox, restart your computer and then open the "Docker Quickstart Terminal" again.

Running Resen

Now you can run Resen! To do this, open an "Anaconda Powershell Prompt" and type "resen" and hit enter! You should see something similar to:

Anaconda Prompt - resen	-	×
		^
Resen 2019.1.0rc1 Reproducible Software Environment		
The second se		

CHAPTER 3

Usage

To use resen, simply enter resen at the command line:

\$ resen

This will open the resen tool:

Type help to see available commands:

[resen] >>> help

This will produce a list of resen commands you will use to manage your resen buckets:

To get more information about a specific command, enter help <command>.

3.1 Resen Workflow

To create, import, export, and remove buckets, we use Resen. Buckets are portable, system independent environments where code can be developed and run. Buckets can be shared between Windows, Linux, and macos systems and all

analysis within the bucket will be run exactly the same. Resen buckets come preinstalled with a variety of common geospace software that can be used immediately in analysis.

The interface to a resen bucket is a jupyter lab server and access to the bucket is provided through a web browser. The user home directory is /home/jovyan. Any mounted storage directories are available in mount.

Below are instructions on how to use Resen to work with buckets. A typical workflow will involve: creation of a bucket, performing scientific data analysis inside the bucket, exporting the bucket and sharing it with colleagues. Collaborators can then import the bucket, perform additional analysis, and then export the bucket for publication in an open access citable repository, such as Zenodo.

3.1.1 Setup a New Bucket

1. Creating a new bucket is performed with the command:

[resen] >>> create

The create command queries the user for several pieces of information required to create a bucket. First it asks for the bucket name. Creating a bucket named amber:

```
Please enter a name for your bucket.
Valid names may not contain spaces and must start with a letter and be less than

$\to 20 characters long.``

>>> Enter bucket name: amber
```

Next, the user is asked to specify the version of resen-core to use:

Please choose a version of resen-core. Available versions: 2019.1.0 >>> Select a version: 2019.1.0

Optionally, one may then specify a local directory to mount into the bucket at /home/jovyan/mount:

```
Local directories can be mounted to either /home/jovyan/work or /home/jovyan/

→mount/ in

a bucket. The /home/jovyan/work location is a workspace and /home/jovyan/mount/_

→is intended

for mounting in data. You will have rw privileges to everything mounted in work,_

→but can

specify permissions as either r or rw for directories in mount. Code and data_

→created in a

bucket can ONLY be accessed outside the bucket or after the bucket has been_

→deleted if it is

saved in a mounted local directory.

>>> Mount storage to /home/jovyan/mount? (y/n): y

>>> Enter local path: /some/local/path
```

Finally, the user is asked if they want jupyterlab to be started:

>>> Start bucket and jupyterlab? (y/n): y

after which resen will begin creating the bucket. Example output for a new bucket named amber with jupyterlab started is:

```
...adding core...
...adding ports...
...adding mounts...
```

(continues on next page)

(continued from previous page)

```
Bucket created successfully!
...starting jupyterlab...
Jupyter lab can be accessed in a browser at: http://localhost:9002/?
→token=e7allfclea42a445807b4e24146b9908e1abff82bacbf6f2
```

2. Check the status of the bucket:

```
[resen] >>> status amber
amber
____
Resen-core Version: 2019.1.0
Status: running
Jupyter Token: e7a11fc1ea42a445807b4e24146b9908e1abff82bacbf6f2
Jupyter Port: 9002
Jupyter lab URL: http://localhost:9002/?
→token=e7a11fc1ea42a445807b4e24146b9908e1abff82bacbf6f2
Storage:
Local
                                        Bucket
⇔Permissions
/some/local/path
                                        /home/jovyan/mount/path
                                                                                 rw
Ports:
Local
               Bucket
9002
               9002
```

At this point, the bucket should have a name, an image, at least one port, and optionally one or more storage locations. Status should be running if the user decided to have jupyterlab started, otherwise the status will be None.

3.1.2 Work with a Bucket

1. Check what buckets are available with list:

```
[resen] >>> listBucket NameDocker ImageStatusamber2019.1.0running
```

If a bucket is running, it will consume system resources accordingly.

2. Stop the bucket amber:

```
[resen] >>> stop amber
```

The status of amber should now be exited:

[resen] >>> list		
Bucket Name	Docker Image	Status
amber	2019.1.0	exited

The bucket will still exist and can be restarted at any time, even after quitting and restarting resen.

3. Start the bucket amber that was just stopped:

[resen] >>> start amber

The status of amber should now be running:

[resen] >>> status		
Bucket Name	Docker Image	Status
amber	2019.1.0	running

4. Export bucket amber:

[resen] >>> export amber

The export command will ask a series of question. First, provide a name for the output *.tar file:

>>> Enter name for output tar file: /path/for/output/amber.tar

If desired, change the default name and tag for the exported image:

```
By default, the output image will be named "amber" and tagged "latest".
>>> Would you like to change the name and tag? (y/n): y
>>> Image name: custom_name
>>> Image tag: custom_tag
```

Specify if you want all mounted directories to be included in the exported bucket. Answering n to this query will allow you to see how large each mount is and specify which you would like to include. Consider excluding any mounts that are not nessesary for the analysis to reduce the size of the output file:

```
The following local directories are mounted to the bucket (total 2212 MB):
/home/usr/mount1
/home/usr/mount2
/home/usr/mount3
>>> Would you like to include all of these in the exported bucket? (y/n): n
>>> Include /home/usr/mount1 [154.68095 MB]? (y/n): y
>>> Include /home/usr/mount2 [2005.28493 MB]? (y/n): y
>>> Include /home/usr/mount3 [53.59823 MB]? (y/n): y
```

Confirm that you want to continue with the export. The values shown should be considered a "high-side" approximation and may not be the actual final size:

This export could require up to 13337 MB of disk space to complete and will. →produce an output file up to 4600 MB. >>> Are you sure you would like to continue? (y/n): y Exporting bucket amber. This will take several minutes.

5. Import a new bucket, amber2, from a tar file amber.tar:

[resen] >>> import

This command will also ask a series of questions. First provide a name for the imported bucket:

```
Please enter a name for your bucket.
Valid names may not contain spaces and must start with a letter and be less_

→than 20 characters long.

>>> Enter bucket name: amber2
```

Specify the *.tar file to import the bucket from:

>>> Enter name for input tar file: /path/to/file/amber.tar

If desired, enter a custom image name and tag. If not provided, the name an image saved on export will be used:

```
>>> Would you like to keep the default name and tag for the imported image?_

→ (y/n): n
>>> Image name: amber2
>>> Image tag: new_tag
```

When a bucket that had mounts is imported, the mounted directories must be extracted and saved on the local machine. Resen will do this automatically, but you have the option to specify where these files should be saved instead of the default location:

```
The default directory to extract the bucket metadata and mounts to is /

default/save/path/resen_amber2.

>>> Would you like to specify and alternate directory? (y/n): y

>>> Enter path to directory: /new_save_path
```

Aside from the existing mounts, you can add new mounts to a imported bucket. This is useful if you would like to repeat the analysis with a different dataset:

```
>>> Mount additional storage to the imported bucket? (y/n): y
>>> Enter local path: /new/local/path/new_mount
>>> Enter bucket path: /home/jovyan/mount/new_mount
>>> Enter permissions (r/rw): r
>>> Mount additional storage to /home/jovyan/mount? (y/n): n
```

Similar to create, you have the option to start jupyter lab immediately after the bucket is imported:

3.1.3 Remove a Bucket

WARNING: This will permanently delete the bucket. Any work that was not saved in a mounted storage directory or downloaded from the bucket will be **permanently lost**.

The user can delete a bucket with the following command:

[resen] >>> remove amber

A bucket that is running needs to be stopped before being removed.
